Thyroglobulin is a protein that is synthesized by the thyroid gland and is the precursor of thyroid hormones. It is a large, complex protein that is composed of four polypeptide chains. The chains are arranged in a tetramer, with two chains of 330 amino acids and two chains of 300 amino acids. The chains are linked by disulfide bonds. The protein is synthesized in the rough endoplasmic reticulum and is then processed in the Golgi apparatus. The final product is a large, complex protein that is secreted into the bloodstream. It is then taken up by the thyroid gland and used to synthesize thyroid hormones.
